# 1. Conversion from Finite automata to regular grammar.

Regular grammar and Finite Automata are equivalent in power.

## Example 1:

Converting a given finite automata accepting  $L = \{n_a(w) \bmod 2 = 0 \text{ and } n_b(w) \bmod 2 = 0\}$  to regular grammar.

$L = \{\text{even number of a's and b's}\}$

Start state of automata will be the start symbol of the grammar.

We start with S, S on seeing terminal a it moves to state A ( $S \rightarrow aA$ ) and on seeing terminal b it moves to state B ( $S \rightarrow bB$ ).

Since S is also the final state, we introduce the production  $S \rightarrow \lambda$ .

$S \rightarrow aA | bB | \lambda$

We will repeat the same for other states and terminal symbols.

$A \rightarrow aS | bC$      $B \rightarrow aC | bS$      $C \rightarrow aB | bA$

So the grammar is,

$S \rightarrow aA | bB | \lambda$

$A \rightarrow aS | bC$

$B \rightarrow aC | bS$

$C \rightarrow aB | bA$

Parse tree for the string abab.

### Example 2:

Converting a given finite automata accepting  $L=\{abw, w \in \{a,b\}^*\}$  to regular grammar.

Start state of automata will be the start symbol of the grammar.

State S on seeing terminal a it goes to state A. So we introduce the production  $S \rightarrow aA$

State A on seeing terminal a it goes to state B. So we introduce the production  $S \rightarrow bB$

State B on seeing terminal a,b remains in state B. So we introduce the production  $B \rightarrow aB|bB$ .

Any final state we introduce the production  $B \rightarrow \lambda$ .

So the grammar is,

$S \rightarrow aA$

$A \rightarrow bB$

$B \rightarrow aB|bB|\lambda$

### Example 3:

Converting given finite automata accepting  $L=\{awa, w \in \{a,b\}^*\}$  to regular grammar.

Start state of automata will be the start symbol of the grammar.

State S on seeing terminal a it goes to state A. So we introduce the production  $S \rightarrow aA$

State A on seeing terminal a,b remains in state A. So ,we introduce the production

$A \rightarrow aA|bA$ .

State A on seeing terminal a it goes to state B. So we introduce the production  $A \rightarrow aB$

Since B is the final state we introduce the production  $B \rightarrow \lambda$ .

We will not encode the production to state D ,as D is a dead state and it will never lead us to the terminal.It is an useless production.

So the grammar is,

**$S \rightarrow aA$**

**$A \rightarrow aA|bA|aB$**

**$B \rightarrow \lambda$**

## 2. Converting Regular grammar to finite automata.

### Example 1:

Convert given regular grammar to finite automata.

$S \rightarrow bS \mid aA$

$A \rightarrow aA \mid bA \mid aB$

$B \rightarrow bbB \mid \lambda$

State S on seeing b remains in S, we will have a self loop on S.

State S on seeing a moves to state A.

A on seeing a and b remains in state A, we will have a self loop on A.

A on seeing a also moves to state B.

B loops on bb, we introduce a new state and loop on bb.

$B \rightarrow \lambda$  indicates B is a final state.

### Example 2:

Convert given regular grammar to finite automata.

$S \rightarrow 01A$

$A \rightarrow 10B$

$B \rightarrow 0A|11$

State S on seeing 01 is moving to state A.

State A on seeing 10 is moving to state B.

State B on seeing 0 moves to state A.

B ends with 11.

### Example 3:

Convert given regular grammar to finite automata.

$A \rightarrow aB | bA | b$

$B \rightarrow aC | bB$

$C \rightarrow aA | bC | a$

State A seeing terminal a is moving to state B.

State A seeing terminal b remains in state B.

State B seeing terminal a is moving to state C.

State B seeing terminal b remains in state B.

State A accepts only b as well.

State C on a moves to final state.
